**BOX PATENT APPLICATION**

Assistant Commissioner for Patents  
U.S. Patent and Trademark Office  
Washington, DC 20231

RE: *U.S. Patent Application Entitled: PROCESSING OF MPEG ENCODED VIDEO FOR TRICK MODE OPERATION*  
*Innventors: Seyfullah H. Oguz; Sorin Faibish; Daniel Gardere; Michel Noury; Wayne W. Duso; Peter Bixby; John Forecast*

Sir:

Transmitted herewith for filing are:

- (1) 84-page patent specification and 26 claims (8 pages) and an abstract (also Figures 1-29 on 25 sheets);
- (2) Two Declarations;
- (3) Assignment and Assignment Cover Sheet;
- (4) Deposit Account Authorization for the total filing fee (listed below).

Assistant Commissioner for Patents  
 June 30, 2000

### FILING FEE CALCULATION

FOR		Small Entity	Large Entity
Total Claims	26 - 20 = 6	x \$9 = \$	or x \$18 = \$ 108.00
Independent Claims	3 - 3 =	x \$39 = \$	or x \$78 = \$ 0.00
Multiple Dependent Claim(s)		+ \$130 = \$	or + \$260 = \$ 0.00
Basic Fee:		+ \$345 = \$	or + \$690 = \$ 690.00
Assignment Recording Fee: (\$40 per assignee)		+ = \$	+ = \$ 40.00
<b>TOTAL FILING FEES</b>		<b>\$ 0.00</b>	<b>\$ 838.00</b>

Pursuant to 37 C.F.R. § 1.10 the Applicants request the Patent and Trademark Office to accept this application and accord a serial number and filing date as of the date this application is deposited with the U.S. Postal Service for Express Mail.

The Assistant Commissioner is authorized to deduct or credit said fees from or to EMC Corporation Deposit Account No. **05-0889/EMC-00-044**.

Please date stamp and return the enclosed postcard to evidence receipt of these materials.

Please forward any reply to this communication directly to our Houston office for docketing purposes. The mailing address and the physical address for courier packages is 750 Bering Drive, Houston, Texas, 77057-2198, and the Houston fax number is 713.787.1440.

Respectfully submitted,

Richard C. Auchterlonie

decoder buffer requirements, transmission orders differ from presentation orders for some frames, so that all the information of the other frames required for decoding a B frame will arrive at the decoder before the B frame.

In addition to the motion compensation techniques for video compression, the MPEG standard provides a generic framework for combining one or more elementary streams of digital video and audio, as well as system data, into single or multiple program transport streams (TS) which are suitable for storage or transmission. The system data includes information about synchronization, random access, management of buffers to prevent overflow and underflow, and time stamps for video frames and audio packetized elementary stream packets embedded in video and audio elementary streams as well as program description, conditional access and network related information carried in other independent elementary streams. The standard specifies the organization of the elementary streams and the transport streams, and imposes constraints to enable synchronized decoding from the audio and video decoding buffers under various conditions.

The MPEG-2 standard is documented in ISO/IEC International Standard (IS) 13818-1, “Information Technology-Generic Coding of Moving Pictures and Associated Audio Information: Systems,” ISO/IEC IS 13818-2, “Information Technology-Generic Coding of Moving Pictures and Associated Audio Information: Video,” and ISO/IEC IS 13818-3, “Information Technology-Generic Coding of Moving Pictures and Associated Audio Information: Audio,” which are incorporated herein by reference. A concise introduction to MPEG is given in “A guide to MPEG Fundamentals and Protocol

1 Analysis (Including DVB and ATSC)," Tektronix Inc., 1997, incorporated herein by  
2 reference.

3 MPEG-2 provides several optional techniques that allow video coding to be  
4 performed in such a way that the coded MPEG-2 stream can be decoded at more than one  
5 quality simultaneously. In this context, the word "quality" refers collectively to features  
6 of a video signal such as spatial resolution, frame rate, and signal-to-noise ratio (SNR)  
7 with respect to the original uncompressed video signal. These optional techniques are  
8 known as MPEG-2 scalability techniques. In the absence of the optional coding for such  
9 a scalability technique, the coded MPEG-2 stream is said to be nonscalable. The MPEG-  
10 2 scalability techniques are varieties of layered or hierarchical coding techniques, because  
11 the scalable coded MPEG-2 stream includes a base layer that can be decoded to provide  
12 low quality video, and one or more enhancement layers that can be decoded to provide  
13 additional information that can be used to enhance the quality of the video information  
14 decoded from the base layer. Such a layered coding approach is an improvement over a  
15 simulcast approach in which a coded bit stream for a low quality video is transmitted  
16 simultaneously with an independently coded bit stream for high quality video. The use of  
17 video information decoded from the base layer for reconstructing the high quality video  
18 permits the scalable coded MPEG-2 stream to have a reduced bit rate and data storage  
19 requirement than a comparable simulcast data stream.

20 The MPEG-2 scalability techniques are useful for addressing a variety of  
21 applications, some of which do not need the high quality video that can be decoded from  
22 a nonscalable coded MPEG stream. For example, applications such as video  
23 conferencing, video database browsing, and windowed video on computer workstations

The MPEG scaling techniques are set out in sections 7.7 to 7.11 of the MPEG-2 standard video encoding chapter 13818-2. They are further explained in Barry G. Haskell et al., Digital Video: An Introduction to MPEG-2, Chapter 9, entitled “MPEG-2 Scalability Techniques,” pp. 183-229, Chapman & Hall, International Thomson Publishing, New York, 1997, incorporated herein by reference. The MPEG scalability techniques include four basic techniques, and a hybrid technique that combines at least two of the four basic techniques. The four basic techniques are called data partitioning, signal-to-noise ratio (SNR) scalability, spatial scalability, and temporal scalability.

Data partitioning is a method of partitioning a single layer coded bit-stream into two classes, including a base layer “partition 0” and an enhancement layer “partition 1”. Partition 0 contains all high level header information as well as some low frequency discrete cosine transform (DCT) coefficients. Partition 1 contains all remaining higher frequency DCT coefficients and end-of-block (EOB) markers. Some syntax elements

1 belonging to partition 0 are redundantly copied to partition 1 to facilitate error recovery.  
2 This duplicated information includes the sequence\_header, GOP\_header, picture\_header,  
3 sequence\_end\_code, sequence\_extension, picture\_extension, and  
4 sequence\_scalable\_extension. This duplication ensures that there is proper  
5 synchronization and recovery following a bit-stream error in the low priority  
6 enhancement layer (partition 1) and introduces very little overhead. With respect to the  
7 single layer coded bit-stream, the separation point between the syntax elements to be  
8 included in the base and enhancement layers is indicated by a priority breakpoint (PBP)  
9 marker. The PBP can be adjusted at every picture slice. The PBP marker partitioning  
10 granularity is at the (run, level) DCT event level of the coded block data. Data  
11 partitioning is especially useful for error resilient video transmission over asynchronous  
12 transfer mode (ATM) networks and other networks where data prioritization is possible.  
13 Data partitioning has a number of shortcomings, including limited flexibility for PBP  
14 adjustment (in terms of partitioning granularity and update frequency), and the  
15 accumulation of drift errors over P pictures due to partially available coefficient  
16 information from a damaged enhancement layer.

SNR scalability is a method of generating a multiplex of bit-streams representing individual layers including a base layer which contains DCT coefficients quantized at a basic moderate quality level, and one or more SNR enhancement layers that contain DCT refinement coefficients intended to enhance the precision of quantized DCT coefficients reconstructed based on the content of all lower layers. Consequently, SNR scalability is also referred to as “Quantization Noise Scalability.” The layers in SNR scalability are all at the same spatial and temporal resolutions but cumulatively produce increasing quality

1 levels starting with the lowest quality at the base layer. The base layer includes all high  
2 level header information, all motion compensation and macroblock (MB) type  
3 information, and coarse quantized DCT coefficient information. The enhancement layers  
4 include quantized DCT refinement coefficient information, and some amount of overhead  
5 information. The slice structure should be the same for all layers. Use of different  
6 quantization matrices in the base and enhancement layers is allowed. The overhead  
7 required by SNR scalability results in a decreased bandwidth utilization efficiency  
8 compared to data partitioning. SNR scalability is especially useful for simultaneous  
9 distribution of standard definition television and high-definition television, error-resilient  
10 video services over ATM and other networks, and multi-quality Video On Demand  
11 (VOD) services. SNR scalability has a number of shortcomings, including increased  
12 complexity and overhead as compared to data partitioning, inflexibility in bandwidth  
13 distribution among the layers primarily due to the fact that all motion information has to  
14 be carried in the base layer, and the shortcoming that no single SNR scalable codec can  
15 eliminate drift errors and also be reliable under lossy enhancement layer transmission.

16 There are two variations to SNR scalability, namely, chroma simulcast and  
17 frequency domain SNR (FDSNR) scalability. Chroma simulcast provides a means for  
18 simultaneous distribution of video services that use 4:2:0 and 4:2:2 chroma subsampling  
19 formats. The associated bit-stream structure has three layers, including a base layer, an  
20 enhancement layer, and a simulcast layer. The base layer is a distribution of video in the  
21 4:2:0 format. The enhancement layer provides SNR enhancement for the luminance  
22 component of the base layer. The simulcast layer includes chrominance components of  
23 the 4:2:2 format.

Spatial scalability provides an ability to decode video at different spatial resolutions without first having to decode an entire (full-size) frame and then decimating it. The base layer carries the lowest spatial resolution version of the video obtained by decimating the original (full-size) video. Enhancement layers carry the differential information required to generate successively higher spatial resolution versions of the video. Spatial scalability supports interoperability between different video resolution and formats, such as support for simultaneous transmission of high definition television and standard definition television, and backward compatibility of MPEG-2 with different standards such as H.262 or MPEG-1. Spatial scalability supports error-resilient video transmission on ATM and other networks. Decoder complexity can scale with channel bandwidth. Spatial scalability has the advantages of a high degree of flexibility in video resolution and formats to be used for each layer, and a high degree of flexibility in achieving bandwidth partitioning between layers. There are no decoder drift problems because there are independent coding loops that are only loosely coupled. Spatial scalability, however, requires significantly increased complexity as compared to data partitioning and SNR scalability.

1           Temporal scalability provides an ability to decode video at different frame rates  
2   without first having to decode every single frame. The base layer carries the lowest  
3   frame rate version of the video coded by itself at the basic temporal rate. This version of  
4   the video is obtained from the original full frame rate version by a temporal down-  
5   sampling operation. The enhancement layers carry the information to construct the  
6   additional frames required to generate successively higher temporal resolution versions of  
7   the video. Additional frames in each enhancement layer are coded with temporal  
8   prediction relative to the frames carried by lower layers. Temporal scalability provides  
9   simultaneous support for different frame rates in the form of downward compatibility  
10   with lower-rate services, such as migration from first generation interlaced high  
11   definition television to high temporal resolution progressive high-definition television.  
12   Temporal scalability supports error-resilient video transmission on ATM and other  
13   networks. Decoder complexity can scale with channel bandwidth. Temporal scalability  
14   has the advantages of providing flexibility in achieving bandwidth partitioning between  
15   layers. There are no decoder drift problems because there are independent coding loops  
16   that are only loosely coupled. Temporal scalability has less complexity and higher  
17   efficiency than spatial scalability. Temporal scalability, however, provides a bandwidth  
18   partitioning flexibility that is more limited than spatial scalability because temporal  
19   scalability uses the same spatial resolution in all layers.

20           Hybrid scalability combines two scalabilities at a time from among SNR, spatial  
21   and temporal scalabilities. A base layer carries a basic quality, spatial and temporal  
22   resolution version of the intended video content. A first enhancement layer carries  
23   differential information required to implement one of the two intended enhancements on

7 . In accordance with one aspect, the invention provides a method of processing  
8 original-quality MPEG coded video to produce reduced-quality MPEG coded video for  
9 trick mode operation. The MPEG coded video includes a set of non-zero AC discrete  
10 cosine transform (DCT) coefficients for 8x8 blocks in I-frames of the MPEG coded  
11 video. The method includes removing non-zero AC DCT coefficients from the 8x8  
12 blocks of I-frames of the MPEG coded video to produce I-frames of reduced-quality  
13 MPEG coded video, and inserting freeze frames in the reduced-quality MPEG coded  
14 video.

15 In accordance with another aspect, the invention provides a data storage device  
16 containing a main file, a fast-forward file and a fast-reverse file. The main file contains  
17 data of an MPEG transport stream including groups of pictures (GOPs). Each GOP  
18 includes an original-quality I-frame and a plurality of P or B-frames. The fast-forward  
19 file contains data of a fast-forward MPEG transport stream including GOPs. Each GOP  
20 in the fast-forward file corresponds to a GOP in the main file, and includes at least one  
21 reduced-quality I frame corresponding to the original-quality I frame in the  
22 corresponding GOP of the main file. The fast-reverse file contains data of a fast-reverse  
23 MPEG transport stream including GOPs. Each GOP in the fast-reverse file  
24 corresponding to a GOP in the main file, and includes at least one reduced-quality I-

1 programmed to respond to a client request for the audio-visual presentation in a reverse  
2 order at a fast rate by reading the fast-reverse file and streaming MPEG data from the  
3 fast-reverse file to the client.

#### 4 5 BRIEF DESCRIPTION OF THE DRAWINGS

6 Other objects and advantages of the invention will become apparent upon reading  
7 the following detailed description with reference to the accompanying drawings, in  
8 which:

9 FIG. 1 is a block diagram of a data network including a video file server  
10 implementing various aspects of the present invention;

11 FIG. 2 is a flowchart of a procedure executed by a stream server computer in the  
12 video file server of FIG. 1 to service client requests;

13 FIG. 3 is a flowchart of a procedure for splicing MPEG clips;

14 FIG. 4 is a flowchart of a procedure for seamless video splicing of MPEG clips;

15 FIG. 5 is a more detailed flowchart of the procedure for seamless video splicing  
16 of MPEG clips;

17 FIG. 6 is a continuation of the flowchart begun in FIG. 5;

18 FIG. 7 is a timing diagram showing a timing relationship between video  
19 presentation units (VPUs) and associated audio presentation units (APUs) in an original  
20 MPEG-2 coded data stream;

21 FIG. 8 is a timing diagram showing a timing relationship between video  
22 presentation units (VPUs) and associated audio presentation units (APUs) for a fast-  
23 forward trick-mode stream;

1           FIG. 9 is a flowchart of a procedure for selection and alignment of audio  
2 presentation units (APUs) in the fast-forward trick-mode stream;

3           FIG. 10 is a flowchart of a procedure for producing a trick-mode MPEG-2  
4 transport stream from a regular MPEG-2 transport stream (TS);

5           FIG. 11 is a diagram illustrating relationships between the MPEG discrete cosine  
6 transform (DCT) coefficients, spatial frequency, and the typical zig-zag scan order;

7           FIG. 12 is a diagram illustrating a relationship between an MPEG-2 coded bit  
8 stream and a reduced-quality MPEG-2 coded bit stream resulting from truncation of high-  
9 order DCT coefficients;

10          FIG. 13 is a flowchart of a procedure for scaling MPEG-2 coded video using a  
11 variety of techniques;

12          FIG. 14 is a flowchart of a procedure for signal-to-noise ratio scaling MPEG-2  
13 coded video using a frequency-domain low-pass truncation (FDSNR\_LP) technique;

14          FIG. 15 is a flowchart of a procedure for signal-to-noise ratio scaling MPEG-2  
15 coded video using a frequency-domain largest-magnitude coefficient selection  
16 (FDSNR\_LM) technique;

17          FIG. 16 is a flowchart of a procedure that selects one of a number of techniques  
18 for finding a certain number “k” of largest values out of a set of “n” values;

19          FIG. 17 is a flowchart of a procedure for finding a certain number “k” of largest  
20 values from a set of “n” values, which is used in the procedure of FIG. 16 for the case of  
21  $k \ll \frac{1}{2} n$ ;

22          FIG. 18 is a diagram of a hash table and associated hash lists;

FIG. 19 is a flowchart of a procedure for finding a certain number “k” of values that are not less than the smallest of the “k” largest values in a set of “n” values beyond a certain amount.

FIG. 20 is a flowchart of modification of the procedure of FIG. 15 in order to possibly eliminate escape sequences in the (run, level) coding of the largest magnitude coefficients;

7           FIG. 21 is a flowchart of a subroutine called in the flowchart of FIG. 20 in order  
8    to possibly eliminate an escape sequence;

FIG. 22 is a first portion of a flowchart of a procedure for scaling an MPEG-2 coded video data stream using the modified procedure of FIG. 20 while adjusting the parameter “k” to achieve a desired bit rate, and adjusting a quantization scaling factor (QSF) to achieve a desired frequency of occurrence of escape sequences;

FIG. 23 is a second portion of the flowchart begun in FIG. 22;

FIG. 24 is a simplified block diagram of a volume containing a main file, a corresponding fast forward file for trick mode operation, and a corresponding fast reverse file for trick mode operation;

17 FIG. 25 is a more detailed block diagram of the volume introduced in FIG. 24;

FIG. 26A is a diagram showing video file access during a sequence of video operations including transitions between the main file, the related fast forward file, and the related fast reverse file;

FIG. 26B shows a script of a video command sequence producing the sequence of  
video play shown in FIG. 26A;

## DESCRIPTION OF ILLUSTRATIVE EMBODIMENTS

With reference to FIG. 1, there is shown a block diagram of a data network 20 linking a number of clients 21, 22, 23 to a video file server 24 implementing various aspects of the present invention. The video file server 24 includes at least one stream server computer 25 and a data storage system 26. The stream server computer 25 has a processor 27 and a network link adapter 28 interfacing the processor to the data network 20. The processor 27 executes a data streaming program 29 in memory 30 in order to stream MPEG coded video in real-time to the clients.

17 In accordance with an aspect of the invention, the stream server computer 25  
18 executes an MPEG scaling program 38 to produce reduced-quality MPEG coded video  
19 from nonscalable MPEG-2 coded video by truncating discrete cosine transform (DCT)  
20 AC coefficients from the coded blocks in the MPEG-2 coded video data. The reduced-  
21 quality MPEG coded video can be produced during ingestion of an MPEG-2 file 32 from  
22 the network 20, and stored in one or more associated files 37. Alternatively, the reduced-  
23 quality MPEG coded video in the files 37 could be produced as a background task from

the MPEG-2 file 32. Reduced-quality MPEG coded video could also be produced in real-time from an MPEG-2 file 33 during streaming of the reduced-quality MPEG coded video from the stream server computer 25 to the network 20. The reduced-quality MPEG coded video is useful for a variety of applications, such as browsing and review of stored MPEG-2 assets for search and play-list generation, bit stream scaling for splicing, and bit-rate adjustment via video quality alteration for services with limited resources.

A typical example of browsing for play-list generation involves searching stored assets in a multi-media data base for segments of a desired content to be included in the play list, and in particular selecting the beginning frame and ending frame of each segment to be included. Such editing occurs often in the broadcast environment for inserting commercials and news clips into pre-recorded television programming, and for editing movies for content and time compression. The decoding technique of the present invention permits a PC workstation 23 to perform the decoding and display in real-time by execution of a software program. An operator can view the video content in a display window 39 in a fast-forward or fast-reverse mode, stop at and resume from freeze frames that are valid "in points" and "out points" for seamless splicing, and select an in-point and out-point for a next segment to be included in the play list. The stream server computer 25 could also include a seamless splicing program 40 providing seamless transitions between video segments that are contiguous in a play list and are from different video clips.

For seamless splicing, it is often necessary to reduce the bitrate for one or more frames at the end of a first segment prior to splicing to a second segment. In this case the bitrate must be reduced to avoid buffer overflow as a result of displaying the original

1 The I frames typically occur once for every 15 frames. Assuming that this convention is  
2 followed in the encoding process, it would be possible to preserve and play each I frame  
3 from each and every group of pictures (GOP), resulting in a 15 times slower temporal  
4 sampling rate, or a 1 to 15 speeding up of motion if the I frames only are played back at  
5 the nominal NTSC rate of approximately 30 frames per second. Consequently, the  
6 content of a 60 minutes duration clip will be covered in 4 minutes. Unfortunately the  
7 average information content per frame for the I frames is more than four times the  
8 average information content of the P and B frames. Therefore, the trick-mode cannot be  
9 implemented simply by transmitting only the I frames for a speed-up by a factor of 15,  
10 because this would need an increase in the TS multiplex rate over the nominal rate.

11 In particular, the average information content of an I frame has been measured to  
12 be about 56374.6 bytes. If the I frames only are transmitted at the standard NTSC rate,  
13 then the bit transmission rate would be:  $8(\text{bits per byte}) * 56,374.6(\text{bytes per frame}) * 29.97(\text{frames per sec.})$  or about 13,516,374.1 bits per second only for the video stream,  
14 which is significantly above - almost 3.38 times - the original rate of 4 megabits per  
15 second used in this test. This calculation, being based on an average quantity, is ignoring  
16 the indispensable need for an actually higher transport rate to provide some safety margin  
17 to handle short-term-sustained large size I frame chains (bursts) which practically always  
18 happen. Clearly, some form of modification in the trick-mode operation definition is  
19 required to handle this problem and pull the bit-rate requirement down to the nominal 4  
20 megabits per second.  
21

22 Two degrees of freedom are available to achieve such a reduction in the required  
23 bit-rate for trick-mode operation. The first is I frame compression quality and the second

1 is a motion speed-up ratio. With respect to compression quality, it is well known that  
2 human observers' perception of image detail degrades with increasing motion speed of  
3 objects in the scene. Based on this fact, the type of D pictures were introduced in MPEG-  
4 1 video syntax for fast visible (forward or reverse) search purposes. (See ISO/IEC 11172-  
5 2: 1993 Information Technology - Coding of moving pictures and associated audio for  
6 digital storage media at up to about 1.5 Mbits/s - Part 2: Video, Annex D.6.6. Coding D-  
7 Pictures, p.102). D pictures make use of only the DC coefficients in intra coding to  
8 produce very low quality (in terms of SNR) reproductions of desired frames which were  
9 judged to be of adequate quality in fast search mode.

10 In order to provide support for enhanced quality trick-mode operation, the quality  
11 of the original I frames can be reduced by the preservation of just a sufficient number of  
12 AC DCT coefficients to meet the bit-rate limitation. Based on experiments with two  
13 standard video test sequences (one encoded at 15 Mbits/sec. and the other at 24  
14 Mbits/sec. and both with I frames only), it is observed that the bandwidth for I frames can  
15 be scaled to one half by keeping about 9 lowest order AC coefficients and eliminating the  
16 rest. This scheme provides good quality even at the full spatial and temporal resolution,  
17 much better than D pictures.

18 The inherent speed-up ratio lower bound imposed by the GOP structure can be  
19 relaxed and further lowered by freeze (P) frame substitution in between genuine (SNR  
20 scaled or non-scaled) I frames. The maximum number of freeze frames that can be  
21 inserted before visually disturbing motion jerkiness occurs, is very likely to depend  
22 heavily on the original GOP structure (equivalently the separation between I frames of  
23 the original sequence) and the original amount of motion in the clip. However, 1, 2 or 3

The MPEG encoder manages the video decoder buffer through decode time stamps (DTS), presentation time stamps (PTS), and program clock reference (PCR) values. When splicing the end of a first clip to the beginning of a second clip, there will be a problem of video buffer management if a duration of time  $DTS_{L1} - T_e$  is different from a duration of time  $DTS_{F2} - PCR_{e2}$  minus one video frame (presentation) interval, where  $DTS_{L1}$  is the DTS at the end of the first clip and indicates the time at which the video decoder buffer is emptied of video data from the first clip,  $T_e$  is the time at which the last video frame's data is finished being loaded into the video decoder buffer,  $DTS_{F2}$  is the DTS of the first frame of the second clip, and  $PCR_{e2}$  is the PCR of the second clip extrapolated from the value of the most recent received genuine PCR record, to the first byte of the picture header sync word of the first video frame in the clip to start. The extrapolation adjusts this most recently received genuine PCR record value by the quotient of the displacement in data bits of the clip from the position where it appears in

the second clip to the position at which video data of the first frame of the second clip begins, divided by the data transmission bit rate for transmission of the clip to the decoder. Because the time  $PCR_{e2}$  must immediately follow  $T_e$ , there will be a gap in the decoding and presentation of video frames if  $DTS_{F2}-PCR_{e2}$  is substantially greater than  $DTS_{L1}-T_e$  plus one video frame interval. In this case, the buffer will not be properly full to begin decoding of the second clip one video frame interval after the last frame of the first clip has been decoded. Consequently, either the second clip will be prematurely started to be decoded or the decoder will be forced to repeat a frame one or more times after the end of the display of the last frame from the first clip to provide the required delay for the second clip's buffer build-up. In the case of a premature start for decoding the second clip, a video buffer underflow risk is generated. On the other hand, in case of repeated frames, the desired frame accuracy for scheduled play-lists is lost besides the fact that neither a precise timing adjustment can be achieved through this procedure.

14 If  $DTS_{F2}-PCR_{e2}$  is substantially less than  $DTS_{L1}-T_c$  plus one video frame interval,  
15 then the decoder will not be able to decode the first frame of the second clip at the  
16 specified time  $DTS_{F2}$  because the last frame of the first clip will not yet have been  
17 removed from the video buffer. In this case a video buffer overflow risk is generated.  
18 Video buffer overflow may present a problem not only at the beginning of the second  
19 clip, but also at a subsequent location of the second clip. If the second clip is encoded by  
20 an MPEG-2 compliant encoder, then video buffer underflow or buffer overflow will not  
21 occur at any time during the decoding of the clip. However, this guarantee is no longer  
22 valid if the  $DTS_{F2}-PCR_{e2}$  relationship at the beginning of the second clip is altered.  
23 Consequently, to avoid buffer problems, the buffer occupancy at the end of the first clip

FIG. 4 shows a flow chart of a seamless video splicing procedure that attains the desired condition just described above. In a first step 141, the first DTS of the second clip is anchored at one frame interval later than the last DTS of the first clip in order to prevent a video decoding discontinuity. Then, in step 142, the procedure branches depending on whether the PCR extrapolated to the beginning frame of the second clip falls just after the ending time of the first clip. If so, then the splice will be seamless with respect to the original video content. Otherwise, the procedure branches to step 143. In step 143, the content of the first clip is adjusted so that the PCR extrapolated to the beginning frame of the second clip falls just after the ending time of the first clip. Therefore the desired conditions for seamless video splicing are achieved.

With reference to FIG. 5, there is shown a more detailed flow chart of a seamless video splicing procedure. In a first step 151, the procedure inspects the content of the first clip to determine the last DTS/PTS of the first clip. This last DTS/PTS of the first clip is designated  $DTS_{L1}$ . Next, in step 152, the procedure inspects the content of the first clip to determine the time of arrival ( $T_e$ ) of the last byte of the first clip. In step 153, the

FIGS. 7 to 10 show further details regarding trick-mode operation. FIG. 7 shows a timing relationship between video presentation units (VPUs) and associated audio presentation units (APUs) in an original MPEG-2 coded data stream, and FIG. 8 shows similar timing for the fast-forward trick-mode stream produced from the original data stream of FIG. 7. (The fast-forward trick-mode stream is an example of a trick-mode stream that could be produced in step 60 of FIG. 2.) The original data stream has successive video presentation units for video frames of type I, B, B, P, B respectively. The trick-mode stream has successive video presentation units for video frames of types I, F, F, I, F where “F” denotes a freeze P (or possibly B) frame. Each I frame and immediately following F frames produce the same video presentation units as a respective I frame in the original data stream of FIG. 7, and in this example, one in every 15 frames in the original data stream is an I frame. Each freeze frame is coded, for example, as a P frame repeating the previous I frame or the previous P-type freeze-frame (in display order). In each freeze frame, the frame is coded as a series of maximum-size slices of macroblocks, with an initial command in each slice indicating that the first macroblock is an exact copy of the corresponding macroblock in the previous frame

1 (achieved by predictive encoding with a zero valued forward motion compensation vector  
2 and no encoded prediction error), and two consequent commands indicating that the  
3 following macroblocks in the slice until and including the last macroblock of the slice are  
4 all coded in the same way as the first macroblock.

For trick-mode operation, there is also a problem of how to select audio presentation units (APU) to accompany the video presentation units that are preserved in the trick-mode stream. Because the video presentation units (VPU) have a duration of  $(1/29.97)$  sec. or about 33.37 msec. and the audio presentation units (APU) have a duration of 24 msec., there is neither a one-to-one correspondence nor alignment between VPUs and APUs. In a preferred implementation, the audio content of a trick-mode clip is constructed as follows. Given the total presentation duration  $(1/29.97)$  sec. or about 33.37 msec. for a single video frame, it is clear that always at least one and at most two 24 msec. long audio presentation units (APU) will start being presented during the end-to-end presentation interval of each video frame. This statement refers to the original clip and does not consider any audio presentation unit whose presentation is possibly continuing as the video frame under consideration is just put on the display. The first of the above mentioned possibly two audio presentation units will be referred to as the aligned audio presentation unit with respect to the video frame under consideration. For example, in FIG. 8, the  $APU_j$  is the aligned audio presentation unit with respect to the  $VPU_i$ . Now, when the I frames are extracted and possibly SNR scaled and possibly further interleaved with a number of freeze P frames in between them to produce the trick-mode video packetized elementary stream (PES), the associated trick-mode audio stream is constructed as follows. For each I type video frame presentation interval (and

FIG. 9 is a flowchart of a procedure for producing the desired sequencing of audio presentation units (APUs) in the fast-forward trick-mode stream. This procedure scans the audio elementary stream in the original MPEG-2 stream to determine the sequence of APUs in the original stream and their presentation-time alignment with the I frames in the video elementary stream of the original MPEG-2 transport stream, while selecting APUs to include in the trick-mode stream. In a first step 171, execution proceeds once the end of the current APU is reached. If the end of the current APU has not entered a new VPU (*i.e.*, the beginning of the current APU is within the presentation time of one VPU and the

FIG. 10 is a flowchart of a procedure for producing a trick-mode stream from an MPEG-2 transport stream (TS). In a first step 181, the MPEG-2 TS is inputted. In step 182, the video elementary stream (VES) is extracted from the TS. In step 183, a concurrent task extracts the audio elementary stream (AES) from the TS. In step 184, I frames are extracted from the VES and valid packetized elementary stream (PES) packets are formed encapsulating the I frames. In step 185, the I frames are SNR scaled, for the high speed cases of the trick-mode. In step 186, P-type freeze frames are inserted into the stream of SNR scaled I frames (in between the scaled I frames), and valid PES packets are formed for the trick-mode VES encapsulating the P-type freeze frames and the SNR scaled I frames. Concurrently, in step 187, appropriate audio access units (from the originally input MPEG-2 TS asset) are selected and concatenated based on the structure of the VES being formed for the trick-mode clip, as described above with reference to FIG. 9, and valid PES packet encapsulation is formed around these audio access units. Finally, in step 188, the trick-mode TS stream is generated by multiplexing the trick-

1

2 The heavy black line through the matrix of coefficients in FIG. 11 denotes the default  
3 zig-zag scan order typically used for MPEG-2 encoding. Listed in this order, the  
4 coefficients are  $C_{11}$ ,  $C_{12}$ ,  $C_{21}$ ,  $C_{31}$ ,  $C_{22}$ ,  $C_{13}$ ,  $C_{14}$ ,  $C_{23}$ ,  $C_{32}$ ,  $C_{41}$ , ...,  $C_{86}$ ,  $C_{77}$ ,  $C_{68}$ ,  $C_{78}$ ,  $C_{87}$ ,  
5  $C_{88}$ . The first coefficient in this zig-zag scan order is the DC coefficient  $C_{11}$  providing  
6 the lowest spatial frequency content in the 8x8 block of pixels, and the last coefficient in  
7 this zig-zag scan order is the coefficient  $C_{88}$  providing the highest spatial frequency  
8 content in the 8x8 block of pixels.

9 FIG. 12 is a diagram illustrating a relationship between an original MPEG-2  
10 coded bit stream 200 and a reduced-quality MPEG-2 coded bit stream 210 resulting from  
11 truncation of high-order DCT coefficients from the original MPEG-2 coded bit stream.  
12 Shown in the original MPEG-2 coded bit stream 200 is a portion of a video PES packet  
13 including DCT coefficients for an 8x8 pixel block. The DCT coefficients include a  
14 differentially coded DC coefficient 201, and three (run, level) events 202, 203, 204  
15 encoding three respective nonzero AC coefficients possibly along with some zero valued  
16 AC coefficients preceding the three nonzero valued ones. The DCT coefficients are  
17 ordered according to the zig-zag scan order shown in FIG. 11 (or possibly according to an  
18 alternate zig-zag scan pattern also supported by the MPEG-2 standard), and AC  
19 coefficients having zero magnitude are described in terms of total counts of consecutive  
20 zero valued coefficients lying in between two nonzero valued coefficients, in the MPEG-  
21 2 coded bit stream. An end-of-block (EOB) code 205 signals the end of the encoded  
22 DCT coefficients for the current block. The reduced-quality MPEG-2 coded bit stream  
23 210 includes a DC coefficient 201' identical to the DC coefficient 201 in the original

1 MPEG-2 coded bit stream 200, and a (run, level) event 202' identical to the (run, level)  
2 event 202 in the original MPEG-2 coded bit stream 200. Second and third (run, level)  
3 events, however, have been omitted from the reduced-quality MPEG-2 bit stream 210,  
4 because an EOB code 205' immediately follows the (run, level) event 202'. Therefore,  
5 the two nonzero high-order AC DCT coefficients encoded by the second and third (run,  
6 level) events 203, 204 have been omitted from the reduced-quality MPEG-2 bit stream  
7 210.

FIG. 13 is a flowchart of a procedure for scaling MPEG-2 coded video using a variety of techniques including the omission of AC DCT coefficients. The procedure operates upon an original-quality MPEG-2 coded video stream by removing AC DCT coefficients in this stream to produce a lower quality MPEG coded video stream. In a first step 221, execution branches to step 222 if the scaled MPEG coded video is to be spatially subsampled. In step 222, the procedure removes any and all DCT coefficients for spatial frequencies in excess of the Nyquist frequency for the downsampled video. For example, if the low-quality video stream will be downsampled by a factor of two in both the vertical and the horizontal directions, then the procedure removes any and all DCT coefficients having a row index (i) greater than four and any and all DCT coefficients having a column index (j) greater than four. This requires the decoding of the (run, level) coded coefficients to the extent necessary to obtain an indication of the coefficient indices. If a sufficient number of the original AC DCT coefficients are removed for a desired bandwidth reduction, then the scaling procedure is finished. Otherwise, execution branches from step 223 to step 224. Execution also continues from step 221 to step 224 if spatial downsampling is not intended.

In step 224, execution branches to step 225 if low-pass scaling is desired. Low-pass scaling requires the least computational resources and may produce the best results if the scaled, low-quality MPEG coded video is spatially downsampled. In step 225, the procedure retains up to a certain number of lowest-order AC DCT coefficients for each block and removes any additional DCT coefficients for each block. This is a kind of frequency domain signal-to-noise ratio scaling (FDSNR) that will be designated FDSNR\_LP. A specific example of the procedure for step 225 will be described below with reference to FIG. 14.

Execution continues from step 224 to step 226 if low-pass scaling is not desired.

In step 226, execution branches to step 227 if largest magnitude based scaling is desired.

Largest magnitude based scaling produces the least squared error or difference between the original-quality MPEG-2 coded video and the reduced-quality MPEG coded video for a given number of nonzero AC coefficients to preserve, but it requires more computational resources than the low-pass scaling of step 225. More computational resources are needed because if there are more nonzero AC coefficients than the desired number of AC coefficients for a block, then the (run, level) events must be decoded fully to obtain the coefficient magnitudes, and additional resources are required to find the largest magnitude coefficients. In step 227, the procedure retains up to a certain number of largest magnitude AC DCT coefficients for each block, and removes any and all additional AC DCT coefficients for each block. This is a kind of frequency domain signal-to-noise ratio scaling (FDSNR) that will be designated FDSNR\_LM. A specific example of the procedure for step 227 will be described below with reference to FIG. 15.

With reference to FIG. 14, there is shown a flowchart of a procedure for scaling MPEG-2 coded video using the low-pass frequency-domain signal-to-noise (FDSNR\_LP) scaling technique. This procedure scans and selectively copies components of an input stream of original-quality MPEG-2 coded data to produce an output stream of reduced-quality MPEG-2 coded video. The procedure is successively called, and each call processes coefficient data in the input stream for one 8x8 block of pixels. No more than a selected number “k” of coded lowest order (nonzero or zero valued) AC coefficients are copied for the block where the parameter “k” can be specified for each block.

In a first step 241 of FIG. 14, the procedure parses and copies the stream of original-quality MPEG-2 coded data up to and including the differential DC coefficient variable-length code (VLC). Next, in step 242, a counter variable “*l*” is set to zero. In

FIG. 15 is a flowchart of a procedure for scaling MPEG-2 coded video using the largest magnitude based frequency-domain signal-to-noise ratio (FDSNR\_LM) scaling technique. This routine is successively called, and each call processes coefficient data in the input stream for one 8x8 block of pixels. No more than a specified number “k” of largest magnitude AC DCT coefficients are copied for the block, and a different number “k” can be specified for each block.

In a first step 261 in FIG. 15, the procedure parses and copies the input stream of original-quality MPEG-2 coded data to the output stream of lower-quality MPEG-2 data up to and including the differential DC coefficient variable-length code (VLC). Then in step 262 all (run, level) event VLCs are parsed and decoded until and including the EOB marker of the current block. The decoding produces coefficient identifiers and corresponding quantization indices representing the quantized coefficient values. In step 263, the quantization indices are transformed to quantized coefficient values. In step 264, the (quantized) coefficients are sorted in descending order of their magnitudes. In step 265, the first “k” coefficients of the sorted list are preserved and the last 63-k AC DCT coefficients in the sorted list are set to zero. In step 266, (run, level) event formation and entropy coding (VLC encoding) are applied to the new set of coefficient values. Finally,

5           In step 288, if the magnitude of the current coefficient is greater than the  
6           magnitude at the end of the list, then execution branches to step 291. In step 291, the  
7           entry at the end of the list is removed. In step 292, a binary search is performed to  
8           determine the rank position of the magnitude of the current coefficient, and in step 293,  
9           the current coefficient index and magnitude are inserted into the list at the rank position.  
10          The list, for example, is a linked list in the conventional fashion to facilitate the insertion  
11          of an entry for the current coefficient at any position in the list. After step 293, execution  
12          loops back to step 288.

13 An approximation technique of coefficient magnitude classification can be used to  
14 reduce the computational burden of sorting by coefficient magnitude. A specific example  
15 is the use of hashing of the coefficient magnitude and maintaining lists of the indices of  
16 coefficients having the same magnitude classifications. As shown in FIG. 18, a hash  
17 table 300 is linked to hash lists 301 storing the indices of classified coefficients. As  
18 shown, the hash table 300 is a list of  $2^M$  entries, where “M” is three, and an entry has a  
19 value of zero if its associated list is empty, and otherwise the entry has a pointer to the  
20 end of the coefficients in its associated list. The lists shown in FIG. 18 have fixed  
21 memory allocations in which the pointers in the hash table also indicate the number of  
22 coefficient indices in the respective hash lists. Alternatively, the hash lists could be  
23 dynamically allocated and linked in the conventional fashion.

1 counter “j” is less than or equal to zero, then the procedure is finished. Otherwise, if the  
2 counter “j” is not less than or equal to zero in step 324, execution loops back to step 321.

The FDSNR\_LM procedure, as described above, in general provides a significant improvement in peak signal-to-noise ratio (PSNR) over the FDSNR\_LP procedure when each procedure retains the same number of non-zero AC DCT coefficients. It has been found, however, that substantially more bits are required for the (run, level) coding of the non-zero AC DCT coefficients resulting from the FDSNR\_LM procedure than those resulting from the FDSNR\_LP procedure, provided that the same coefficient quantization and scanning method is used. Therefore, the FDSNR\_LM procedure provides at best a marginal improvement in rate-distortion (PSNR as a function of bit rate) over the FDSNR\_LP procedure unless the non-zero AC DCT coefficients for the FDSNR\_LM procedure are quantized, scanned, and/or (run, level) coded in a fashion different from the quantization, scanning, and/or (run, level) coding of the coefficients in the original MPEG-2 clip. A study of this problem resulted in a discovery that it is sometimes possible to reduce the number of bits for (run, level) coding of coefficients for an 8x8 block including a given number of the non-zero largest magnitude AC DCT coefficients if additional coefficients are also (run, level) coded for the block.

The (run, level) coding of the non-zero AC DCT coefficients from the FDSNR\_LM procedure has been found to require more bits than from the FDSNR\_LP procedure due to an increased occurrence frequency of escape sequences for the (run, level) coding. The increased frequency of escape sequences is an indication that the statistical likelihood of possible (run, level) combinations for the non-zero AC DCT coefficients selected by the FDSNR LM procedure is different from the statistical

3

4                      The FDSNR\_LP procedure selected AC DCT coefficients have (run, level)  
5      symbol statistics that are similar to the statistics of ordinary MPEG-2 coded video, and  
6      therefore the FDSNR\_LP AC DCT coefficients have a similar frequency of occurrence  
7      for escape sequences in comparison to the ordinary MPEG-2 coded video. In contrast,  
8      the FDSNR\_LM procedure selects AC DCT coefficients resulting in (run, level)  
9      combinations that are less likely than the combinations for ordinary MPEG-2 coded  
10     video. This is due to two reasons. First, the FDSNR\_LM procedure selects AC DCT  
11     coefficients having the highest levels. Second, the FDSNR\_LM procedure introduces  
12     higher run lengths due to the elimination of coefficients over the entire range of  
13     coefficient indices. The result is a significantly increased rate of occurrence for escape  
14     sequences. Escape sequences form the most inefficient mode of coefficient information  
15     encoding in MPEG-2 incorporated into the standard so as to cover important but very  
16     rarely occurring coefficient information.

17                    In order to improve the rate-distortion performance of the scaled-quality MPEG-2  
18     coded video from the FDSNR\_LM procedure, the non-zero AC DCT coefficients  
19     selected by the FDSNR\_LM procedure should be quantized, scanned, and/or (run, level)  
20     coded in such a way that tends to reduce the frequency of the escape sequences. For  
21     example, if the original-quality MPEG-2 coded video was (run, level) coded using  
22     TABLE 0, then the largest magnitude coefficients should be re-coded using TABLE 1  
23     because TABLE 1 provides shorter length VLCs for some (run, level) combinations

1 having higher run lengths and higher levels. It is also possible that re-coding using the  
 2 alternate scan method instead of the zig-zag scan method may result in a lower frequency  
 3 of occurrence for escape sequences. For example, each picture could be (run, level)  
 4 coded for both zig-zag scanning and alternate scanning, and the scanning method  
 5 providing the fewest escape sequences, or the least number of bits total, could be selected  
 6 for the coding of the reduced-quality coded MPEG video.

7 There are two methods having general applicability for reducing the frequency of  
 8 escape sequences resulting from the FDSNR\_LM procedure. The first method is to  
 9 introduce a non-zero, "non-qualifying" AC DCT coefficient of the 8x8 block into the list  
 10 of non-zero qualifying AC DCT coefficients to be coded for the block. In this context, a  
 11 "qualifying" coefficient is one of the k largest magnitude coefficients selected by the  
 12 FDSNR\_LM procedure. The non-qualifying coefficient referred to above, must be lying  
 13 in between two qualifying AC DCT coefficients (in the coefficient scanning order) that  
 14 generate the (run, level) combination causing the escape sequence. Moreover, this non-  
 15 qualifying coefficient must cause the escape sequence to be replaced with two shorter  
 16 length VLCs when the AC DCT coefficients are (run, level) coded. This first method has  
 17 the effect of not only decreasing the number of bits in the coded reduced-quality MPEG  
 18 video in most cases, but also increasing the PSNR.

19 The qualifying AC DCT coefficient causing the escape sequence that is first in the  
 20 coefficient scanning order will be simply referred to as the first qualifying coefficient.  
 21 The qualifying AC DCT coefficient causing the escape sequence that is second in the  
 22 coefficient scanning order will be simply referred to as the second qualifying coefficient.  
 23 For example, suppose the qualifying coefficients in zig-zag scan order for an 8x8 block

include  $C_{51}$  followed by  $C_{15}$  having a level of 40. If only the qualifying coefficients were (run, level) coded for the microblock,  $C_{15}$  would result in a run length of 3, because there are a total of three non-qualifying coefficients ( $C_{42}$ ,  $C_{33}$ , and  $C_{24}$ ) between  $C_{51}$  and  $C_{15}$  in the scan order. Therefore,  $C_{15}$  would have to be coded as an escape sequence, because a run of 3 and level of 40 does not have a special symbol. In this example, the escape sequence is in effect caused by a first qualifying coefficient, which is  $C_{51}$ , and a second qualifying coefficient, which is  $C_{15}$ . This escape sequence can possibly be eliminated say, if  $C_{24}$  is a non-zero, non-qualifying coefficient of the block,  $C_{24}$  has a level of 5 or less, and  $C_{24}$  is (run, level) coded together with the qualifying coefficients. For example, assuming that  $C_{24}$  has a level of 5, and using the MPEG-2 (run, level) coding TABLE 1, then  $C_{24}$  has a run length of two and is coded as the special symbol 0000 0000 1010 0s, where "s" is a sign bit, and  $C_{15}$  now has a run length of 0 and is coded as the special symbol 0000 0000 0010 00s. Such a consideration clearly applies to the rest of the non-zero non-qualifying coefficients lying in between the two qualifying coefficients producing the escape sequence. In the above example, these non-qualifying coefficients are  $C_{42}$  and  $C_{33}$ .

Whether or not an escape sequence can be eliminated from the (run, level) coding of the qualifying coefficients can be determined by testing a sequence of conditions. The first condition is that the second qualifying coefficient must have a level that is not greater than the maximum level of 40 for the special (run, level) symbols. If this condition is satisfied, then there must be a non-zero non-qualifying AC DCT coefficient that is between the first and second qualifying coefficients in the coefficient scanning order. If there is such a non-qualifying coefficient, then the combination of its level and

1 execution branches from step 348 to step 349 to search for additional non-zero non-  
2 qualifying AC DCT coefficients that would eliminate the escape sequence. In other  
3 words, steps 342 to 347 are repeated in an attempt to find additional non-zero non-  
4 qualifying AC DCT coefficients that would eliminate the escape sequence. If no more  
5 such non-qualifying coefficients are found, as tested in step 350, execution returns with a  
6 successful search result. Otherwise, execution branches from step 350 to step 351 to  
7 select the non-qualifying coefficient giving the shortest overall code word length and/or  
8 the largest magnitude for the best PSNR, and execution returns with a successful search  
9 result. For example, for each non-qualifying coefficient that would eliminate the escape  
10 sequence, the total bit length is computed for the (run, level) coding of the non-qualifying  
11 coefficient and the second qualifying coefficient. Then a search is made for the non-  
12 qualifying coefficient producing the shortest total bit length, and if two non-qualifying  
13 coefficients which produce the same total bit length are found, then the one having the  
14 largest level is selected for the elimination of the escape sequence.

15 A second method of reducing the frequency of occurrence of the escape  
16 sequences in the (run, level) coding of largest magnitude AC DCT coefficients for an 8x8  
17 block is to change the mapping of coefficient magnitudes to the levels so as to reduce the  
18 levels. Reduction of the levels increases the likelihood that the (run, level) combinations  
19 will have special symbols and therefore will not generate escape sequences. This second  
20 method has the potential of achieving a greater reduction in bit rate than the first method,  
21 because each escape sequence can now be replaced by the codeword for one special  
22 symbol, rather than by the two codewords as is the case for the first method. The second  
23 method, however, may reduce the PSNR due to increased quantization noise resulting

1 from the process producing the lower levels. Therefore, if a desired reduction of escape  
2 sequences can be achieved using the first method, then there is no need to perform the  
3 second method, which is likely to reduce the PSNR. If the first method is used but not all  
4 of the escape sequences have been eliminated, then the second method could be used to  
5 possibly eliminate the remaining escape sequences.

6 The mapping of coefficient magnitudes to the levels can be changed by decoding  
7 the levels to coefficient magnitudes, changing the quantization scale factor (qsi), and then  
8 re-coding the levels in accordance with the new quantization scale factor (qsi). The  
9 quantization scale factor is initialized in each slice header and can also be updated in the  
10 macroblock header on a macroblock basis. Therefore it is a constant for all blocks in the  
11 same macroblock. In particular, the quantization scale factor is a function of a  
12 q\_scale\_type parameter and a quantizer\_scale\_code parameter. If q\_scale\_type = 0, then  
13 the quantizer scale factor (qsi) is twice the value of q\_scale\_code. If q\_scale\_type = 1,  
14 then the quantizer scale factor (qsi) is given by the following table, which is the right half  
15 of Table 7-6 on page 70 of ISO/IEC 13838-2:1996(E):

17	<u>quantizer_scale_code</u>	<u>quantization scale factor (qsi)</u>

In a preferred method for generation of trick mode files, the quantization scale factor is adjusted in order to achieve a desired reduction in the escape sequence occurrence frequency resulting from the modified FDSNR\_LM procedure, and the number (k) of largest magnitude coefficients is adjusted in order to achieve a desired reduction in bit rate. A specific implementation is shown in the flow chart of FIGS. 22-23. In a first step 361, the number (k) of largest magnitude AC coefficients per 8x8 block is initially set to a value of 9, and the quantization scaling factor (QSF) is initially set to a value of 2. Then conversion of the I frames of an original-quality MPEG-2 coded video clip to a lower quality level begins. When a picture header is encountered in step 362,

7 In step 376, if the average bit rate is not greater than the threshold TH3, then  
8 execution continues to step 379. In step 379, the average bit rate is compared to a lower  
9 threshold TH4. If the average bit rate is less than the threshold TH4, then execution  
10 branches from step 379 to step 380, where the number (k) of non-zero largest magnitude  
11 AC DCT coefficients per 8x8 block is compared to a limit value of 13. If the number (k)  
12 is less than or equal to 13, then execution continues to step 381 to increment the number  
13 (k). After step 378 or 381, execution continues to step 382. In step 382, execution  
14 continues to step 383 if a backtrack option is selected. In step 383, an attempt is made to  
15 re-code the last slice for the scaled quality picture using the adjusted value of the number  
16 (k) of non-zero largest magnitude AC DCT coefficients per block. After step 383,  
17 execution loops back to step 362 of FIG. 22 to continue generation of the scaled quality  
18 clip. Execution also loops back to step 362 of FIG. 22 after: step 377 if the value of (k) is  
19 not greater than or equal to 6; step 379 if the average bit rate is not less than the threshold  
20 TH4; step 380 if the value of (k) is not less than or equal to 13; and step 382 if the  
21 backtrack option has not been selected. Coding of the scaled quality clip continues until  
22 the end of the original quality clip is reached in step 364 of FIG. 22, in which case  
23 execution returns.

In a preferred implementation, a fast forward trick mode file and a fast reverse trick mode file are produced from an original-quality MPEG-2 coded video main file when the main file is ingested into the video file server. As shown in FIG. 24, a volume generally designated 390 is allocated to store the main file 391. The volume 390 includes an allocated amount of storage that exceeds the real file size of the main file 391 in order to provide additional storage for meta-data 392, the fast forward trick file 393, and the fast reverse trick file 394. The trick files are not directly accessible to clients as files; instead, the clients may access them thorough trick-mode video service functions. With this strategy, the impact on the asset management is a minimum. No modification is needed for delete or rename functions.

Because the volume allocation is done once for the main file and its fast forward and fast reverse trick mode files, there is no risk of lack of disk space for production of the trick files. The amount of disk blocks to allocate for these files is computed by the video service using a volume parameter (vsparams) specifying the percentage of size to allocate for trick files. A new encoding type is created in addition to types RAW for direct access and MPEG2 for access to the main file. The new encoding type is called EMPEG2, for extended MPEG2, for reference to the main file plus the trick files. The video service allocates the extra file size only for these files.

For the transfer of these files to archive or to another video file server, it would be useful to transfer all the data even if it is a non-standard format. For the FTP copy-in, a new option is added to specify if the source is in the EMPEG2 format or if it is a standard MPEG2 file. In the first case, the copy-in should provide the complete file 390. In the second case, the video service allocates the extra size and the processing is the same as

FIG. 25 is a more detailed diagram of the volume 390, showing additional meta-data and related data structures. The Inode 401 includes 4 disk blocks containing a file-system oriented description of the file. The Meta-data (MD) directory 402 includes 4 disk blocks describing each entry of the meta-data area 392. The entries of the meta-data area 392 include a description of the MPEG-2 meta-data 403, a description of the trick files header meta-data 404, and a description of the GOP index meta-data 405. The MPEG-2 meta-data 403 includes 15 disk blocks maximum.

21           The trick files header 404 includes 1 disk block, which specifies the beginning of  
22   free area (end of last trick file) in blocks, the number of trick files couple (FF FR), and  
23   for each trick file, a speed-up factor, a block address of the GOP index, a block address of

The GOP index includes 2024 disk blocks. The GOP index specifies, for each GOP, a frame number, a pointer to the MPEG-2 data for the GOP in the main file, and various flags and other attributes of the GOP. The flags indicate whether the GOP entry is valid and whether the GOP is open or closed. The other attributes of the GOP include the maximum bit rate, the average bit rate, the AAU size in bytes, the APU duration in seconds, the audio PES packet starting locations, the AAU starting locations, the AAU PTS values, and the decode time stamp (DTS) and the value of the program clock reference (PCR) extrapolated to the first frame of the GOP. The size of all the data preceding the main file is, for example, 1 megabyte.

There is one GOP index 406 for both the fast forward file 393 and the fast reverse file 394. The GOP index 406 of the trick files is different than the GOP index 405 of the main file. The GOP index 406 of the trick files contains, for each GOP, the byte offset in the trick file forward of the TS packet containing the first byte of the SEQ header, the frame number in the fast forward file of the GOP (the same value for the fast reverse file can be computed from this value for the fast forward file), the frame number in the original file of the first frame of the GOP, and the byte offset in the original file of the same frame (to resume after fast forward or reverse without reading the main GOP index).

The GOP index 405 for the main file and the GOP index 406 for the fast forward  
and fast reverse trick files provides a means for rapidly switching between the normal

video-on-demand play operation during the reading of the main file, and the fast-forward play during the reading of the fast-forward file, and the fast-reverse play during the reading of the fast reverse file. For example, FIG. 26A illustrates the read access to various GOPs in the main file, fast forward file, and fast reverse file, during a play sequence listed in FIG. 26B. Due to the presence of down-scaled I frames and possibly consequent freeze frames in the trick mode files, the video buffer verifier (V BV) model for a trick mode file is different than the V BV model of the main file. Consequently, the mean video decoder main buffer fullness levels can be significantly different for these files. For example, a transition from the main file to one of the trick files will usually involve a discontinuity in the mean video decoder main buffer fullness level, because only the I frames of the main file correspond to frames in the trick files, and the corresponding I frames have different bit rates when the trick mode I frames are scaled down for a reduced bit rate. An instantaneous transition from a trick file back to the main file may also involve a discontinuity especially when freeze frames are inserted between the I frames for trick mode operation. To avoid these discontinuities, the seamless splicing procedure of FIGS. 3 to 6 as described above is used during the transitions from regular play mode into trick mode and similarly from trick mode back into the regular play mode. Through the use of the seamless splicing procedure to modify the video stream content, for example for the “Seamless Splice” locations identified in FIG. 26A, the video decoder main buffer level will be managed so as to avoid both overflows and underflows leading to visual artifacts.

It is desired to copy in and out of the volume 390 with or without the meta-data  
392 and the trick files 393, 394. This is useful to export and/or import complete files

without regenerating the trick files. The file encoding type is now recognized as a part of the volume name. Therefore there can be multiple kinds of access to these files. The read and write operations are done by derivations of the class file system input/output (FSIO) which takes into account the proper block offset of the data to read or write. There is one derivation of FSIO per encoding type, providing three different access modes. EMGP3, MPEG2, and RAW. EMPEG2 accesses the whole volume from the beginning of the meta-data array, and in fact provides access to the entire volume except the inode 401, but no processing is done. MPEG2 access only the main part of the asset with MPEG processing, including file analyze and meta-data generation in a write access. RAW access only the main part of the asset without processing. These access modes are operative for read and write operations for various access functions as further shown in FIG. 27.

During a record operation, the video service allocates a volume and computes the number of block to allocate using the volume parameter giving the percentage to add for the trick files. Then, the size in blocks given to the stream server is the main part size only without the extension for the trick files. This avoids using the reserved part of the volume when the effective bit rate is higher than the requested bit rate. At the end of a record operation or a FTP copyin operation, the video service calls a procedure CMSPROC\_GETATTR, and the stream server returns the actual number of bytes received and the actual number of blocks used by the main file plus the meta-data. The same values are returned for both MPEG2 and EMPEG2 files. The video service computes again the file extension to manage the trick files and adjust the number of allocated blocks.

1 Both trick files forward and reverse are generated by the same command. First,  
2 the trick file forward is generated by reading the main file. The trick file GOP index is  
3 built and kept in memory. During this generation, only the video packets are kept. PCR,  
4 PAT and PMT will be regenerated by the MUX in play as for any other streams. The  
5 audio packets are discarded. This ensures that there is enough stuffing packets for the  
6 PCR reinsertion. For this, a stuffing packet is inserted every 30 milliseconds.

7 Then using the GOP index, the trick file forward is read GOP by GOP in reverse  
8 order to generate the trick file reverse. The same GOPs are present in both files. The  
9 only modification done is an update of the video PTS, which must be continuous. Then,  
10 the GOP index is written on disk. This avoids reading again the file while generating the  
11 second trick file. The GOP index size is: 24 times the GOP number. In the worst case  
12 (the file is assumed not to be 1 frame only), there are 2 frames per GOP and 30 frames  
13 per second. So for 1 hour in fast forward, the GOP index size is:  $(24 \times 3600 \times 30) / 2 =$   
14 1296000 bytes. This will be the case for a 4 hour film played at 4 times the normal  
15 speed. Therefore, this GOP index can be kept in memory during the trick file generations  
16 without risk of memory overflow.

17 The read and write rate are controlled to conserve bandwidth on the cached disk  
18 array. The bandwidth reserved for these generations is a parameter given by the video  
19 service. It is a global bandwidth for both read and writes. The number of disk I/O per  
20 seconds is counted so as not to exceed this bandwidth.

21 The trick files header update is done once when both the fast forward and fast  
22 reverse trick files and the GOP index have been successfully written.

1           Playing a file is done with the CM\_MpegPlayStream class. Fast forward  
2 (reverse) can only be requested when we are in the paused state. The current frame on  
3 which we are paused is known from the MpegPause class. This frame is located in the  
4 GOP index of the trick file. Then the clip start point and length are modified in the Clip  
5 instance with the trick file position computed from the beginning of the clip. So, the Clip  
6 class handle these trick files in a manner similar to the main file. The current logical  
7 block number is updated with the block address in the trick file recomputed from the  
8 beginning of the main clip. In fact, a seek is performed in the trick file as it was part of  
9 the main file, which is totally transparent for the ClipList and Clip classes. The transition  
10 from fast forward to pause is handled in a similar fashion. The clip start and length and  
11 the logical block number are again updated. The smooth transitions from pause to fast  
12 forward and from fast forward to pause are done in the same way as for regular play.  
13 There is a splicing from the pause stream to the play stream.

The class hierarchy for trick file handling is shown in FIG. 28. The MpegFast, MpegFastForward and MpegFastReverse class handles the GOP generation from the initial file. This is the common procedure for building the GOP whatever the source and the destination. RealTimeFastFwd and RealTimeFastRev are the class instantiated when a real time fast forward (reverse) has to be done. They manage the real-time buffer flow to the player. There is a derivation of the methods takeBuffer and returnBuffer which uses the base class to build the GOP in the buffer to be played. The main file access is done using a buffer pool.

TrickFilesGenerate is the class instantiated to generate trick files forward and reverse. It inherits from TrickFileAccess the methods for reading the original file some

```

1      ulong_t      framesNumber;      /* frames number in each trick file (FWD and
2          REV) */
3      ulong_t      gopNumber;          /* GOP number of each file */
4  };
5
6  struct EMPEG2info_t{
7      MPEG2info_t      MPEG2info;
8      trickFilesInfo_t      trickFiles<>;
9  };
10
11  union encodingInfo_t switch (encoding-t enc){
12      case ENC_MPEG:
13          MPEG2info_t      MPEG2info;
14      case ENC_EMPEG2:
15          EMPEG2info_t      EMPEG2info;
16      default:
17          void;
18  };

```

20 The video service software includes a new procedure (VCMP\_TRICKFILESGEN) for  
 21 trick file generation, which uses the following structures:

```

23  struct VCMPtrickgenres_t{

```

could be the last non-zero AC DCT coefficient in the scan order. Alternatively, the non-zero AC DCT coefficient having the smallest magnitude could be removed so long as its removal does not cause an escape sequence.

When the module 414 removes a non-zero AC DCT coefficient from a 8x8 block, it sends the number of bits removed to the adder/subtractor 422. In a preferred implementation, the operations of the adder/subtractor 422, integrator 423, and limiter 424 are performed by a subroutine having a variable representing the integrated value. During each computational cycle, the variable is incremented by the number of bits to be removed per computational interval, and whenever the module 414 removes a non-zero AC DCT coefficient from a 8x8 block of the audio-visual transport stream, the variable is decremented by the number of bits removed.

Although the system in FIG. 29 has been described for achieving a slight reduction in bit rate of the MPEG-2 audio-visual transport stream 411 for combining multiple transport stream to produce a multiplexed MPEG-2 transport stream, it should be apparent that it could be used for obtaining relatively large reductions in bit rate. In this case, the module 414 would use the procedure of FIGS. 14, 15 or preferably FIG. 20, and a multi-level comparator 424 would be used instead of a single-level comparator 424. The multi-level comparator would determine a desired number of non-zero coefficients to discard per 8x8 block based on the value of the output of the integrator 423. The maximum number of non-zero AC coefficients to keep for each 8x8 block (i.e., the value of the parameter "k"), for example, would be determined by subtracting the number of non-zero AC DCT coefficients in the 8x8 block from the desired number to discard, and

limiting this difference to no less than a predetermined fraction of the average number of non-zero AC coefficients per 8x8 block.

In view of the above, there has been described a method of processing original-quality MPEG coded video to produce reduced-quality MPEG coded video for trick mode operation by removing non-zero AC DCT coefficients from the 8x8 blocks of I-frames of the MPEG coded video to produce I-frames of reduced-quality MPEG coded video, and inserting freeze frames in the reduced-quality MPEG coded video. Preferably, the original-quality MPEG coded video is stored in a main file, and the reduced-quality MPEG coded video is stored in a fast-forward file and a fast-reverse file. The fast forward file and the fast reverse files contain reduced-quality I frames corresponding to original-quality I frames in the main file. A reading of the main file produces an MPEG transport stream for an audio-visual presentation at a normal rate, a reading of the fast-forward file produces an MPEG transport stream of the audio-visual presentation in a forward direction at a fast rate, and a reading of the fast-reverse file produces an MPEG transport stream of the audio-visual presentation in a reverse direction at a fast rate. Preferably, the files share a volume that include at least one GOP index associating the corresponding I frames of the files, and a file server is programmed to access the volume to produce an MPEG transport stream and response to client video access requests by seamlessly splicing between normal play and fast-forward play or fast-reverse play.

4        5.        The method as claimed in claim 2, which includes responding to a client video  
5        access request by seamless splicing between an MPEG coded video stream from the main  
6        file and an MPEG coded video stream from the trick mode file.

6. The method as claimed in claim 1, which further includes ingesting the original-quality MPEG coded video into a file server and storing the original-quality MPEG coded video in a main file, producing the I-frames of reduced-quality MPEG coded video from the original-quality MPEG coded video ingested into the file server, storing a first copy of the I-frames of reduced-quality MPEG coded video in a fast-forward trick mode file, and storing a second copy of the I-frames of reduced-quality MPEG coded video in a fast-reverse trick mode file, the fast-forward trick mode file including a first sequence of the I-frames of reduced-quality MPEG video in a forward order for streaming MPEG coded video from the fast-forward trick mode file as the fast-forward trick mode file is read for a fast-forward presentation of the MPEG coded video, and the fast-reverse trick mode file including a second sequence of the I-frames of reduced-quality MPEG video in a reverse order for streaming MPEG coded video from the fast-reverse trick mode file as the fast-reverse trick mode file is read for a fast-reverse presentation of the MPEG coded video

12. A data storage device containing a main file, a fast-forward file and a fast-reverse file, the main file containing data of an MPEG transport stream including groups of pictures (GOPs), each GOP including an original-quality I-frame and a plurality of P or B-frames, the fast-forward file containing data of a fast-forward MPEG transport stream including GOPs, each GOP in the fast-forward file corresponding to a GOP in the main file and including at least one reduced-quality I frame corresponding to the original-quality I frame in the corresponding GOP of the main file, the fast-reverse file containing data of a fast-reverse MPEG transport stream including GOPs, each GOP in the fast-reverse file corresponding to a GOP in the main file and including at least one reduced-quality I-frame corresponding to the original-quality I frame in the corresponding GOP of the main file, wherein a reading of the main file produces an MPEG transport stream for an audio-visual presentation at a normal rate, a reading of the fast-forward file produces an MPEG transport stream of the audio-visual presentation in a forward direction at a fast rate, and a reading of the fast-reverse file produces an MPEG transport stream of the audio-visual presentation in a reverse direction at a fast rate.

## ABSTRACT

Original-quality MPEG coded video is processed to produce reduced-quality MPEG coded video for trick mode operation by removing non-zero AC DCT coefficients from the 8x8 blocks of I-frames of the MPEG coded video to produce I-frames of reduced-quality MPEG coded video, and inserting freeze frames in the reduced-quality MPEG coded video. Preferably, the coded video is stored in a main file, a fast-forward file and a fast-reverse file. The fast forward file and the fast reverse files contain reduced-quality I frames corresponding to original-quality I frames in the main file. A reading of the main file produces an MPEG transport stream for an audio-visual presentation at a normal rate, a reading of the fast-forward file produces an MPEG transport stream of the audio-visual presentation in a forward direction at a fast rate, and a reading of the fast-reverse file produces an MPEG transport stream of the audio-visual presentation in a reverse direction at a fast rate. Preferably, the files share a volume that includes at least one GOP index associating the corresponding I frames of the files.

```

The flowchart illustrates the process for generating a TS stream from a trick mode stream. It begins with a start node labeled "TRICK MODE STREAM". The process then branches into two parallel paths. The left path involves extracting the Video elementary stream (VES) from the input MPEG-2 TS, performing I frame extraction and valid PES formation, SNR scaling of the I-frames-only PES, and finally freezing P frame insertion and valid PES formation. The right path involves extracting the Audio elementary stream (AES) and selecting and concatenating appropriate audio access units based on the structure of the VES in the trick mode clip and valid PES encapsulation around these audio access units. Both paths converge at a final step: TS stream generation by multiplexing the above video PES into a system info (SI) and audio PES carrying TS skeleton. The process concludes with an "END" node.

**DECLARATION**

As a below named inventor, I hereby declare that:

My residence, post office address and citizenship are as stated below next to my name.

I believe I am the original, first and sole inventor (if only one name is listed below) or the below named inventors are the original, first and joint inventors (if plural names are listed below) of the subject matter which is claimed and for which a patent is sought on the invention entitled **PROCESSING OF MPEG ENCODED VIDEO FOR TRICK MODE OPERATION**, the Specification of which:

☒ is attached hereto.  
☐ was filed on \_\_\_\_\_ as Application Serial No. \_\_\_\_\_.

I hereby state that I have reviewed and understand the contents of the above-identified specification, including the claims.

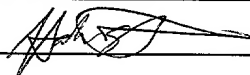

I acknowledge the duty to disclose to the Patent and Trademark Office all information known to me to be material to patentability of the subject matter claimed in this application, as "materiality" is defined in Title 37, Code of Federal Regulations, § 1.56.

I hereby direct that all correspondence and telephone calls be addressed to Richard C. Auchterlonie, Howrey Simon Arnold & White, LLP, 750 Bering Drive, Houston, Texas 77057-2198, (713) 787-1400.

I HEREBY DECLARE THAT ALL STATEMENTS MADE OF MY OWN KNOWLEDGE ARE TRUE AND THAT ALL STATEMENTS MADE ON INFORMATION AND BELIEF ARE BELIEVED TO BE TRUE; AND FURTHER THAT THESE STATEMENTS WERE MADE WITH THE KNOWLEDGE THAT WILLFUL FALSE STATEMENTS AND THE LIKE SO MADE ARE PUNISHABLE BY FINE OR IMPRISONMENT, OR BOTH, UNDER SECTION 1001 OF TITLE 18 OF THE UNITED STATES CODE AND THAT SUCH WILLFUL FALSE STATEMENTS MAY JEOPARDIZE THE VALIDITY OF THE APPLICATION OR ANY PATENT ISSUED THEREON.

## PROCESSING OF MPEG ENCODED VIDEO FOR TRICK MODE OPERATION

Inventor's Full Name:	Seyfullah	H.	Oguz
Inventor's Signature:			
Country of Citizenship:	Turkey	Date:	6/29/00
Residence Address: (street, number, city, state, and/or country)	1630 Worchester Rd., Apt. 402C, Framingham, MA 01702		
Post Office Address: (if different from above)			

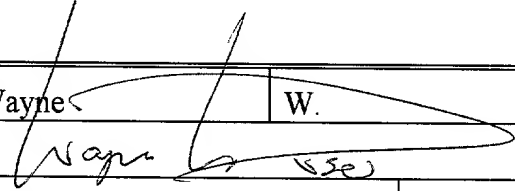

Inventor's Full Name:	Sorin		Faibish
Inventor's Signature:			
Country of Citizenship:	Israel	Date:	6/29/00
Residence Address: (street, number, city, state, and/or country)	11 Selwyn Rd., Newton, MA 02461		
Post Office Address: (if different from above)			

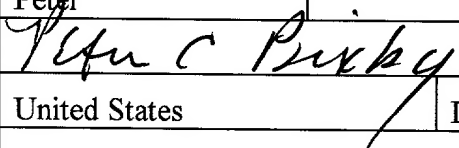

Inventor's Full Name:	Daniel		Gardere
Inventor's Signature:			
Country of Citizenship:	France	Date:	
Residence Address: (street, number, city, state, and/or country)	8, rue Paul Valery, 78180, Montigny-Le-Bretonneux, France		
Post Office Address: (if different from above)			

## PROCESSING OF MPEG ENCODED VIDEO FOR TRICK MODE OPERATION

Inventor's Full Name:	Michel		Noury
Inventor's Signature:			
Country of Citizenship:	France	Date:	
Residence Address: (street, number, city, state, and/or country)	44 rue des Casseaux, Villebon Sur Yette, F-91140, France		
Post Office Address: (if different from above)			

Inventor's Full Name:	Wayne	W.	Duso
Inventor's Signature:			
Country of Citizenship:	United States	Date:	29-Jun-00
Residence Address: (street, number, city, state, and/or country)	6 Timari Drive, Shrewsbury, MA 01545		
Post Office Address: (if different from above)			

Inventor's Full Name:	Peter		Bixby
Inventor's Signature:			
Country of Citizenship:	United States	Date:	6/29/00
Residence Address: (street, number, city, state, and/or country)	41 Lackey Street, Westborough, MA 01581		
Post Office Address: (if different from above)

**DECLARATION**

As a below named inventor, I hereby declare that:

My residence, post office address and citizenship are as stated below next to my name.

I believe I am the original, first and sole inventor (if only one name is listed below) or the below named inventors are the original, first and joint inventors (if plural names are listed below) of the subject matter which is claimed and for which a patent is sought on the invention entitled **PROCESSING OF MPEG ENCODED VIDEO FOR TRICK MODE OPERATION**, the Specification of which:

☒ is attached hereto.  
☐ was filed on \_\_\_\_\_ as Application Serial No. \_\_\_\_\_

I hereby state that I have reviewed and understand the contents of the above-identified specification, including the claims.

I acknowledge the duty to disclose to the Patent and Trademark Office all information known to me to be material to patentability of the subject matter claimed in this application, as "materiality" is defined in Title 37, Code of Federal Regulations, § 1.56.

I hereby direct that all correspondence and telephone calls be addressed to Richard C. Auchterlonie, Howrey Simon Arnold & White, LLP, 750 Bering Drive, Houston, Texas 77057-2198, (713) 787-1400.

I HEREBY DECLARE THAT ALL STATEMENTS MADE OF MY OWN KNOWLEDGE ARE TRUE AND THAT ALL STATEMENTS MADE ON INFORMATION AND BELIEF ARE BELIEVED TO BE TRUE; AND FURTHER THAT THESE STATEMENTS WERE MADE WITH THE KNOWLEDGE THAT WILLFUL FALSE STATEMENTS AND THE LIKE SO MADE ARE PUNISHABLE BY FINE OR IMPRISONMENT, OR BOTH, UNDER SECTION 1001 OF TITLE 18 OF THE UNITED STATES CODE AND THAT SUCH WILLFUL FALSE STATEMENTS MAY JEOPARDIZE THE VALIDITY OF THE APPLICATION OR ANY PATENT ISSUED THEREON.
